Sumathi and Samuel Selvaraj

1.0 Introduction:
The Earth’s climate has always been changing. Any change in the energy from the sun received at the Earth’s surface will therefore affect the climate. The radiant energy received from Sun is responsible for the development and continuous existence of life on Earth. The radiation is received at the earth’s surface in an attenuated form because it is subjected to absorption and scattering as it passes through the earth’s atmosphere [1]. Absorption occurs primarily because of the presence of ozone and water vapor in the atmosphere, and to a lesser extent due to other gases (like CO₂, NO₂, CO, O₂ and CH₄) and particulate matter. The scattering occurs due to all gaseous molecules as well as particulate matter in the atmosphere. Solar radiation received at the earth’s surface without change of direction i.e in line with the sun is called beam or direct radiation. The radiation received at the earth’s surface from all parts of the sky’s hemisphere is called diffuse radiation. The sum of direct radiation and diffuse radiation is referred to as total or global radiation. The study of solar Ultraviolet radiation has received considerable attention in the past few years (Al-Aruri (1998), Khogali and Al-Bar1992) because of its biological, ecological and physical effects produced by short-wave radiation received at the surface of the earth.

Ultraviolet radiation is a specific part of the sun’s total spectrum of wavelength. Ultraviolet (UV) radiation which composes 8.73% of the solar spectrum (3) in the outer space is generally classified into three wavelength regions namely Ultraviolet A (315-400nm), Ultraviolet B (280-315nm) and Ultraviolet C (100-280nm)[2]. UV A radiation is normally reflected back from atmosphere. Presence of ozone and oxygen in the stratosphere results in the absorption of nearly all UV-C radiation (200-280nm) and Solar UV-B radiation (280-315nm) significantly. Solar UV-B radiation that reaches the ground is after complicated scattering and absorption process in the atmosphere and at the earth surface. The main geophysical variables that affect surface UV radiation are clouds, ozone, surface albedo and aerosols.[4] UV radiation intensity is gradually increasing in the world due to depletion of Ozone layer[7]. Ozone layer depletion is due to release of gases like CO₂, CO and Chloro flora Carbons. While it is essential to reduce the release of these gases into atmosphere, it is also important to measure and project UV exposure on earth.

2.0 Data and Methodology:
In the present paper a correlation between the ultraviolet (UV) and the global solar radiation(G) over Chennai were computed. Sunshine data of Chennai have been obtained from Regional Meteorological centre, Chennai. Daily data were obtained for the period of August2011 to December 2011. Using sunshine data in the Regression equation (Sivamadhavi &Samuel Selvaraj (8), the global radiation were computed daily for the same
period. Data were observed using UV light meter model: UV-340A. The instrument can measure low range of 1999 uw/cm² and high range of 19990 uw/cm² with accuracy + or – 4% FullScale +2 digits. UV radiation reading were taken every half an hour and sum of these values is taken as daily total value.

The following empirical models were used to estimate the daily global radiation.

\[ \frac{H}{H_o} = 0.0460 + 0.1429 S - 0.0106 S^2 \] (For August) \((1)\)

\[ \frac{H}{H_o} = -0.1274 + 0.1500 S - 0.0715 S^2 \] (For September) \((2)\)

\[ \frac{H}{H_o} = 0.2885 + 0.0328 S - 0.0003 S^2 \] (For October) \((3)\)

\[ \frac{H}{H_o} = 0.2613 + 0.0363 S \] (For November) \((4)\)

\[ \frac{H}{H_o} = 0.1697 + 0.0593 S - 0.0012 S^2 \] (For December) \((5)\)

The daily data of ultraviolet and global solar radiation at Chennai are illustrated in fig. 1 & 2. Fig 3 shows the relationship between computed and observed values of UV radiation. MBE value is an indication of the average deviation of the computed values from the corresponding observed data and can provide information on long term permanence of the model, the lower MBE the better is the long term model calculation. A positive MBE value indicates the amount of overestimation in the computed UV. RMSE provides information on the short term permanence which is a measure of variation of computed values from the corresponding observed data and can provide information.

(i) Mean Bias Error (MBE) defined as

\[ \text{MBE} = \frac{1}{N} \Sigma (I-P) \]

Where N denotes the total number of observations, P is the observed value and I is the computed value

(ii) Root Mean Square Error (RMSE) defined as

\[ \text{RMSE} = \left[ \frac{1}{N} \Sigma (I-P)^2 \right]^{1/2} \]

(iii) MAPE=\[\frac{\Sigma |I-P/P|}{N\times 100}\]

Empirical Formula of Ultraviolet Solar Radiation Investigated over Chennai:

Many types of correlation were tried to find out the best fit between Global and UV data. The best of the relationship was observed in Linear Correlation.[9,10]

$$UV \text{ radiation} = a\text{(Global radiation)} + b$$ ..............................................(1)

where $a$ and $b$ are regression coefficients which depend on the weather parameters of the location. The values of $a$ and $b$ are 0.0157 and 0.3721. The obtained values for correlation coefficient was 0.942498.

Verification of the empirical equation

Accordingly the empirical relationship investigated (equation 1) becomes

$$UV \text{ radiation} = 0.0157\text{(Global radiation)}+0.3721$$ ..............................................(2)

The observed data of global solar radiations are introduced in equation 2 to calculate the corresponding values of UV radiation. The estimated data of ultraviolet solar radiation were compared with corresponding observed data. The results are illustrated by fig.(3). & Fig.(4)
Fig. 4: Scatter plot of observed and computed UV data

From the figure it can be seen that the estimated values of UV solar radiation are in agreement with the observed values.

Table 1: shows the errors (MBE, RMSE and MAPE) between the observed and computed UV Radiation

3.0 Conclusions:
The daily values of UV radiation and daily global horizontal solar radiation (300-280nm) at Chennai have been analyzed in this study. The linear regression equation

\[ \text{Ultraviolet radiation} = 0.0157(\text{Global radiation}) + 0.3721 \]

can calculate the UV radiation on any date when sunshine hours is available. Assessment of the UV radiation variability and trend is of considerable interest because of the environmental and health risk caused by an increase in this radiation whereas the UV measurement network is sparingly distributed and the UV data series are short.
